¹⁸F-FDG POSITRON EMISSION-COMPUTERIZED TOMOGRAPHY (FDG PET-CT)

EXAMINATION: 18F-FDG PET-CT scan, vertex to mid-thigh.

CLINICAL HISTORY: [To be completed by referring clinician]

COMPARATIVE STUDY: No prior study available for comparison.

PROCEDURE: Approximately 60 minutes after the intravenous administration of 18F-FDG, PET images were acquired from the vertex to mid-thigh using 3-D acquisition. A low-dose CT was obtained for attenuation correction and anatomical localisation. Images were displayed in the axial, coronal and sagittal planes. Maximum Standardized Uptake Value (SUV_{max}) normalized for body weight was used.

TECHNIQUE:

Height: 175 cm

Weight: 72 kg

Fasting blood sugar: _____ mg/dl

Site of injection: _____

Normal blood pool liver demonstrates SUV_{max} 2.5

SCAN FINDINGS:

HEAD & NECK: FDG-avid lesion in Head/Neck with SUV_{max} 16.5 (metabolic volume 22.1 mL). FDG-avid lesion in Head/Neck with SUV_{max} 12.9 (metabolic volume 14.3 mL).

THORAX: FDG-avid lesion in Thorax with SUV_{max} 8.4 (metabolic volume 6.1 mL).

ABDOMEN / PELVIS: No hypermetabolic lesion is seen in this region. The liver, spleen, pancreas and bowel show physiological tracer distribution.

BONES / BONE MARROW: No FDG-avid / non-avid skeletal lesion is noted in this region.

CONCLUSIONS:

- Tumor Positive — FDG-avid disease in the head & neck with nodal involvement.
- 3 FDG-avid lesion(s) detected (highest SUV_{max} 16.5), consistent with metabolically active disease.
- Deauville score: 5.
- PERCIST status: Active Disease (Baseline).
- Total metabolic tumour volume 42.5 mL; total lesion glycolysis 310.2.
